Abstract Crowdfunding emerged recently as an alternative way of funding for start-up projects. Our dataset consists of 16,666 investments made at Companisto, one of the largest crowdfunding platforms in Europe. Using cluster analysis based on individual investment decisions, we find that crowdfunders differ in their investment strategies and motivations. We can distinguish three types of crowdfunders: Casual Investors, Crowd Enthusiasts, and Sophisticated Investors. The types also vary in their response to project quality signals, project-related information reducing the degree of uncertainty, and social influence by fellow investors. We conclude that crowdfunders are anything but a homogeneous group. Instead, they are motivated by different factors and respond to different signals when making investment decisions.

1 Introduction

Early-stage start-ups are confronted with considerable difficulties in attracting external finance. A barrier to the acquisition of financial resources arises from imperfections in capital markets, which are conventionally attributed to the existence of information asymmetries (Carpenter and Petersen 2002; Cassar 2004; Colombo and Grilli 2007). Specifically, entrepreneurs possess more information about their abilities and the prospects of their new business than outsiders. As start-ups often lack assets to provide as collateral, and because they lack the financial history and the track record necessary to establish their reputation, investors cannot readily observe venture quality and may thus be reluctant to provide funding (Shane and Stuart 2002).

Recent advancements in information and communication technologies (ICTs) have led to financial innovations that ease the way in which capital demand meets supply and thus improve the efficiency of capital markets (Agrawal et al. 2014). Among these innovations, crowdfunding (CF) is emerging as one prominent financing alternative for early-stage entrepreneurial projects (Block et al. 2018a; Bruton et al. 2015).

The recent phenomenon of CF promises to be a new way to match entrepreneurs looking for funds and potential financiers. In contrast to traditional financiers, CF allows funds to be raised by rather small amounts from a large group of individuals, the “crowd.” CF grew

exponentially in the last years (Massolution 2016) giving reason to believe that it will develop into an important funding channel in the future.

The success of CF stimulated an increasing body of research devoted to determinants of the individual decision to fund a specific project. This research highlights the significance of quality signals (Ahlers et al. 2015; Li et al. 2016; Ralcheva and Roosenboom 2016; Nitani and Riding 2017; Piva and Rossi-Lamastra 2018; Bapna 2019), social influence (Herzenstein et al. 2011; Zhang and Liu 2012; Lee and Lee 2012; Hekman and Brussee 2013; Vulkan et al. 2016; Crosetto and Regner 2018; Hornuf and Schwiembacher 2018; Vismara 2018), and social capital (Mollick 2014; Colombo et al. 2015; Giudici et al. 2018; Vismara 2016). Using data from Kickstarter, a pre-ordering based CF platform, Lin et al. (2014) demonstrate that different types of crowdfunders can have different motives of backing a project leading to different funding strategies. Also, the information on which crowdfunders base their individual decision, ranging from quality signals to information about the activity of other crowdfunders, are not alike across the different types.

Our paper builds on the approach of Lin et al. (2014) but focuses on equity-based CF or crowdfunding (CI). In the USA, specific rules of the Jumpstart Our Business Start-ups (JOBS) Act were implemented only in May 2016. Thus, only limited US data on CI exists so far. By analyzing data from Companisto, one of the largest CI platforms in Europe, our study is the first, to the best of our knowledge, to provide valuable insights about crowdfunder heterogeneity. Our dataset consists of 16,666 investments into 28 projects made by 7474 funders at Companisto.

Our analysis shows that investors differ in their motivations and investment strategies. We identify the following three types: a relatively small group is very active and experienced (“Sophisticated Investors”), a sizable group of funders is motivated by pro-social/community factors (“Crowd Enthusiasts”), and the majority of funders seem mostly concerned about monetary returns (“Casual Investors”). Furthermore, these identified crowdfunder types react in distinct ways to project quality signals sent by the creators of start-up projects and information observed from the investment decisions of fellow crowdfunders, when selecting among investment opportunities. These insights about investor heterogeneity contribute to a better understanding of crowdfunding with practical implications for platforms and entrepreneurs.

The remainder of this paper is structured as follows. Section 2 discusses the related literature, and Sect. 3 describes our data source, the crowdfunding platform Companisto. We derive our typology of crowdfunders in Sect. 4. In Sect. 5, we explore differences in investment behavior among these investor types. Section 6 concludes.

2 Background literature

To address the problems of information asymmetry involved in the financing of entrepreneurial projects, professional investors individually design their financing contracts (Gompers and Lerner 2001; Wong et al. 2009). This allows them to separate the allocation of cash flow rights, voting rights, board rights, liquidation rights, and other control rights such as staged capital infusion. As crowdfunding (CI) caters to a large number of investors, tailor-made contracts can hardly be implemented resulting in the use of highly standardized contracts. Thus, CI contracts provide only little ex-ante protection against problems of asymmetric information (Kortleben and Vollmar 2012; Hornuf and Schwiembacher 2016). Since most crowdfunders are less experienced in evaluating the actual value of a business idea compared to professional investors, the problem of information asymmetry is especially pronounced in the setting of CI. Even if some securities regulators took initial steps towards the alleviation of these issues (Hornuf and Schwiembacher 2017), there is still a great concern about the possible exploitation of less sophisticated investors (Hildebrand et al. 2017).

In particular, the identification of valuable investment opportunities and the monitoring of the investee remain a key challenge in CI (Agrawal et al. 2014). Against this backdrop, recent research on CF and CI has been devoted to understanding the identification of worthwhile investments under asymmetric information between investor and campaign initiator. One part of this literature addresses the entrepreneurial perspective. For example, Mollick (2014) conducted a study on the determinants of success and failure of CF projects listed on Kickstarter. He found that project quality signals such as a video description of the project are correlated to fundraising success. Moreover, the size of an entrepreneur’s social network is found to be a determinant of successful fundraising. Similarly emphasizing the beneficial role of social capital, Hekman and Brussee

(2013) and Giudici et al. (2018) stress the importance of social networks for signaling project quality to potential investors.

The first study trying to assess the crowd's response to quality signals within CI has been conducted by Ahlers et al. (2015) using data from ASSOBS, an Australian CI platform on which entrepreneurs sell equity shares to their investors. Their findings support the importance of human capital (proxied by the number of board members in the management team and the share of board members holding an MBA degree) as an effective quality signal that increases the number of investors. Likewise, providing financial forecasts in their offering documents (e.g., a financial disclaimer stating forecasts of future earnings) is positively correlated with the number of investors. Moreover, an increase in the percentage of equity offered to investors resulted in a lower expected number of investors.

Subsequent studies confirm the importance of human capital as an effective quality signal for CI. Piva and Rossi-Lamastra (2018) analyze data from an Italian platform (SiamoSoci) and find that entrepreneurs' business education and their experience are success determinants. Nitani and Riding (2017) study data from four European platforms and confirm the relevance of entrepreneurs' education. Using data from the Chinese site Dajiatou, also Li et al. (2016) empirically confirm the importance of human capital.

Another potential quality signal is certification by a third party. Ralcheva and Roosenboom (2016) analyze data from Crowdcube and find that backing by a business angel, grants, and protected intellectual property rights (via patents, trademarks, or copyrights) significantly increase success chances. Bapna (2019) conducts a randomized experiment at an anonymized CI platform and finds that certification by an expert intermediary increases the tendency to invest, however, only when combined with other signals (a prominent affiliate or social proof).

Hornuf and Schwienbacher (2018) investigate the reaction of crowdfunders following the investment decisions of their peers. They document the presence of general herding behavior in their analysis of individual investment decisions among 60 CI campaigns, covering investments on Seedmatch and Innvestment. Moreover, Vulkan et al. (2016) analyze data from SEEDRS and show that having a strong start is a vital campaign success determinant. Broadening the understanding of social influence in the context of CI,

Vismara (2018) demonstrates how information cascades among investors can form. He finds that a higher number of investors within the first 5 days of a campaign to increase the number of subsequent investors, the total funding amount, and hence the probability of a successful funding campaign. The number of early investors turned out to be significantly higher when public profile investors have been present within the first 5 days of a campaign. Relatedly, Kim and Viswanathan (2018) identify investors on Appbackr, a CF platform for mobile applications, as experts if they have already developed an app or if they have prior investment experience. They show that investors without specialized expertise emulate the investment decision of these experts.

Finally, some studies investigate the role of within-campaign communication signals. Hornuf and Schwienbacher (2018) find that investors posting comments on the product or market have a positive impact on the number of investments the next day. Block et al. (2018a) show that especially updates about new developments of the start-up have a positive effect on funding. Also, Li et al. (2016) report the importance of project updates as a success determinant.

Lin et al. (2014) identify four distinct groups of crowdfunders on Kickstarter based on their motivations to back specific projects: active backers, trend followers, the altruistic, and the general crowd. Active backers are found to be mainly motivated by social and reputational benefits. Altruistic backers appear to be less risk-averse, primarily motivated by supporting the idea of a project regardless of its popularity or potential risk of failure, in contrast to trend followers. Additionally, these four types of investors also differ in their responses to signals of social capital and social influence. For instance, when it comes to the funding decision, trend followers and active backers are more likely to back projects which have already been backed by a larger number of other funders than the group of altruistic investors. Referring to social capital, measured as the number of projects backed by the project creators themselves, trend followers are less likely to respond to this type of quality signal compared to the general crowd. See Ryu and Kim (2016) for related evidence based on survey data.

These findings give reason to assume that the "crowd" is not a homogeneous community and some studies on crowdfunding started to segregate the crowd. Hervé et al. (2019) and Mohammadi and Shafi

(2018) show that female crowdfunders behave more risk averse than male ones, while Hornuf and Schmitt (2016) and Günther et al. (2018) show that a local bias exists among crowdfunders. Furthermore, Wallmeroth (2019) reports that large pledges (more than EUR 5000) at Companisto make up 3.2% of all pledges but account for about half of the raised funds. Our study builds on this research and goes a step further as it systematically categorizes investors based on their characteristics. We identify distinct investor types and explore how these different types make their investment decisions. As stressed by Mochkabi and Volkmann (2018) in a recent survey article on crowdfunding, such a typology of investors should provide valuable insights about the crowd.

3 Dataset

Our unique dataset is hand-collected from the website of the German CI platform Companisto. Founded in 2012, Companisto is one of the leading CI platforms in Europe and the one currently with the largest market share in Germany (Crowdfunding-Monitor 2017). By the end of December 2014, the platform had 39,007 registered users and gathered a total of EUR 21,253,840 for the 44 projects it hosted. A minimum ticket size of EUR 5 allows essentially anyone to partake in a start-up project. Companisto pools the investments of the crowd via a special purpose entity, Companisto Venture Capital GmbH. Under the “all-or-nothing” model of crowdfunding, project creators set a funding goal and do not receive any pledges unless that goal is reached. In case the start-up project fails to meet the funding goal, Companisto Venture Capital GmbH returns the pledged money to the would-be investors. Moreover, investment shares in start-up projects are allocated on a first-come, first-serve basis. Accordingly, project creators set an overall funding limit, which is typically higher than the funding goal, and stop selling securities when they reach this limit. From the perspective of the investors, losing the principal amount invested represents the highest risk they are exposed to (for example, in the case of insolvency of a start-up project).

The objective of our study is to identify different types of crowdfunders showing different preferences and to reveal how these different crowdfunder types make their backing decisions according to their preferences. For this purpose, the data collection process

covers every investment that has been made throughout all the campaigns (including the amount of each investment and the date of investment) in addition to data about the campaigns themselves (e.g., the business idea, awards won, the involvement of external financiers, financial statements, the education of the project creators, the updates made by the project creator, and comments that were left by investors).

We only consider funding campaigns which ran for the first time on Companisto. Second time funding campaigns, representing follow-up financing, have a strong tendency to attract funders due to their attention gathered in the first financing round. This might affect investors’ choice set of alternatives and their investment decision more profoundly than their preferences do. For this reason, we excluded investments in second run campaigns in order to avoid potential distortion of the analysis. Thus, the final dataset that is used for the empirical analysis comprises information on 16,666 investments made by 7474 funders in 28 start-up projects listed on Companisto from June 6, 2012 to December 21, 2014.¹

All projects reached their goal, and have thus been successfully funded, within 8 to 123 days. The average campaign attracted 595 investors, received EUR 216,878, made 12 updates, and received 134 comments. The average investment is EUR 364, and it occurred 20 days after the start of the campaign. The average investor invested EUR 402.28 in 2.23 projects and commented 1.6 times.

Our analytical approach is to use these data for (i) a cluster analysis that categorizes investors into different types and (ii) then test whether the resulting types respond distinctly to project quality signals of start-up projects and information observed from the investment decisions of fellow crowdfunders. For the cluster analysis, we use investor-level variables, see Sect. 4.2.1 for details. Our analysis of the response to quality signals considers data at the investment level; see Sect. 5.3 for further description of the respective variables. Table 1 displays descriptive statistics of the 28 CI projects, as well as summary statistics at the investor and investment level.

¹ See Table 7 in the Appendix for background information about these projects.

4 Typology of crowdfunders

Crowdfunders usually do not have the financial sophistication and investment experience of professional entities or individuals, such as banks, venture capitalists, or business angels (Freear et al. 1994). Hence, they are likely to evaluate start-up projects and creators in different ways. In the following, we identify determinants of a crowdfunder's funding decision helping us to identify an investor typology.

4.1 What drives crowdfunders to fund a project?

In their multidisciplinary review of the crowdfunding literature, Gleasure and Feller (2016) distinguish between the following motivations among crowdfunders: paying for financial/material benefits, for social benefits, and for participation.

Funders engaging in CI receive equity or equity-like arrangements in return for their investment. Thus, the expectation of *financial benefits* of an investment is a natural motivator for their engagement. Moysidou and Spaeth (2016), for instance, report that perceived financial benefits play a dominant role in the decision making of crowdfunders.

Besides extrinsic factors that may explain contributions of the crowd, funders may be intrinsically motivated, for instance, by *social benefits*. Gerber et al. (2012) document that funders participate on CF platforms, because they like to support creator and cause. They want to be of valuable assistance in the entrepreneur's effort to realize the project idea. Funders supporting the cause may have an interest in securing the creativity and originality of the idea as they are afraid that with tapping into traditional channels of financing the creator's idea has to be compromised in order to get the product out. Altruistic behavior has also been found by Galak et al. (2011) studying lenders on the crowdlending website Kiva.org. In the context of CI, Bretschneider and Leimeister (2017) provide survey evidence that "simply liking a venture" is a positive determinant of the investing decision. Similarly, Daskalakis and Yue (2017) find that interest and excitement are the top drivers in a survey of European crowdfunders. Also Cholakova and Clarysse (2015) confirm non-financial motives among crowdfunders, although their impact on the decision to invest seems smaller in comparison to monetary motives.

A distinct intrinsic motivation is *participation*. Belleflamme et al. (2014) propose that crowdfunders experience "community benefits" when they pledge to a project of their liking. Gerber et al. (2012) find that crowdfunders are motivated by being part of a trusting and creative community. The relevance of such drivers has also been confirmed within other online communities by Kraut and Resnick (2011). Moreover, survey responses in Bretschneider and Leimeister (2017) indicate that crowdfunders are motivated by the possibility to participate in and influence the development process of the start-up's product. Finally, Vismara (2019) uses the introduction of a regulatory framework in the UK that distinguishes between professional and restricted investors. Professionals aim to maximize their funds, while the latter follow a community logic.

4.2 Cluster analysis

We investigate whether the "crowd" can be differentiated into distinct investor types. For this purpose, we perform an explorative cluster analysis sorting crowdfunders based on similarities in their previous investment histories. To determine investor profiles and investment strategies, we consider the three proposed motivations among crowdfunders (i.e., financial, social, community benefits) and their experience/sophistication. The input variables for the cluster analysis are described in the following. Table 1 displays their descriptive statistics.

4.2.1 Variables

Projects indicates the number of investment projects in a crowdfunder's portfolio during the period of analysis. This variable reflects investor experience and activity as well as the degree of portfolio diversification (Lin et al. 2014).

Invested amount represents the average of all investments made by a crowdfunder. The average investment is indicative of investor knowledge and expertise (Homuf and Schwienbacher 2018). More sophisticated and experienced investors may conduct more extensive due diligence of a start-up project. They naturally invest higher amounts as the transaction costs of examining the start-up make smaller investments unprofitable. Both variables, *Projects* and *Invested amount*, are used in the cluster analysis to capture the influence of experience on crowdfunder behavior. The variable *Projects*

Table 1 Descriptive statistics of the study variables

	Count	Unit	Mean	SD	Min	Median	Max
Project-level variables							
Funding duration	28	Days	65.21	33.72	8	60.50	123
Funding target	28	€	28,571.43	8908.71	25,000	25,000	50,000
Funding amount	28	€	216,877.90	203,665.10	41,290	127,767.5	940,650
PhD	28	Dummy	0.14	0.36	0	0	1
Team members	28	Integer	4.11	1.47	2	4	8
Awards	28	Dummy	0.18	0.39	0	0	1
Financial forecast	28	Dummy	0.21	0.42	0	0	1
Ties	28	Dummy	0.57	0.50	0	1	1
Innovativeness	28	Dummy	0.29	0.46	0	0	1
Investors	28	Integer	595.20	303.60	264	475	1621
Updates	28	Integer	12.14	4.96	4	11.50	25
Comments	28	Integer	134.35	86.03	40	97.50	325
Investment-level variables							
Investment amount	16,666	€	364.36	1069.14	5	100	25,000
Days after project start	16,666	Days	20.08	26.90	0	8	441
Investor-level variables							
Projects	7474	Integer	2.23	2.93	1	1	28
Invested amount	7474	€	402.28	1192.40	5	100	25,000
Investors	7474	Integer	794.48	361.93	264	702	1621
Comments	7474	Integer	1.60	6.74	0	0	219
Innovativeness	7474	Rational	36.65	42.30	0	16.67	100

also indicates a crowdfunder's focus on financial benefits (i.e., portfolio diversification as a risk-reducing strategy).

Investors is the average number of investors per project in the investor's portfolio. The number of prior investors among funded projects can reveal insights into an investor's sense of community and its perceived benefits. Crowdfunders enjoying community benefits do so because they put their hearts together striving for a common purpose (Gerber et al. 2012). In the cluster analysis, the variable *Investors* thus allows us to assess whether a crowdfunder is motivated by being part of a project.

Comments is the number of comments an investor posted on Companisto. Posted comments include, for example, responses to updates of the project creators or comments and questions of other investors. Such comments may contain information about the product or market development, possible product improvements or even the offer of personal help to the project creators. Comments are commonly used to evaluate an individual

crowdfunder's engagement in the CI community (Mollick 2014; Hornuf and Schwienbacher 2018). We use the variable *Comments* as an indicator of experience and of a crowdfunder's drive to participate in a start-up community.

Innovativeness captures the innovativeness of an investor's portfolio. It measures the share of innovative start-up projects relative to the total number of funded projects. We consider a start-up project as innovative if (1) intellectual property protection, such as patents or trademarks, has been applied for, (2) the start-up pursues a significant R&D strategy, (3) the start-up serves a market in which there are no direct competitors, and (4) the start-up is the only supplier of its service or product on the market. Information to evaluate the innovativeness of a start-up project are taken from the project description on Companisto. Prior research shows that more innovative start-up projects raise higher amounts of capital and account for a higher number of investors than less innovative ones (Le Pendevan 2016). In the cluster analysis, we employ the variable

Innovativeness to distinguish pro-social motivations as driver of engagement in CI. Crowdinvestors with a higher share of innovative projects in their portfolio might be driven by the desire to support projects that otherwise would suffer from severe funding gaps.

4.2.2 Method

Cluster analysis is a multivariate technique that sorts different objects into groups by maximizing within-group similarities and between-group differences. The identification of clusters is thus empirically based instead of guided by theory.

In this study, we used a two-stage clustering procedure where a hierarchical clustering was employed as a prior step to determine the appropriate number of clusters for subsequent non-hierarchical clustering (Ketchen and Shook 1996). This approach is shown to lead to superior clustering solutions and to increase the validity of the final clusters obtained (Milligan 1980; Punj and Stewart 1983). For both stages of the clustering procedure, we calculated distance matrices using the Euclidean distance measure.

In the first stage, a pre-clustering with the single linkage method was processed to eliminate potential outliers (Jiang et al. 2001). Twenty-eight crowdinvestors have been identified as outliers and were excluded from further analysis. The main procedure was performed using Ward's minimum-variance method. This hierarchical method treats every object as a separate cluster at the beginning of the algorithm. The clusters are then successively joined together into groups until only a single cluster remains. The objective of Ward's method is to join two clusters at each step such that the variance for the joined cluster is minimized (and the variance between clusters is maximized). Ward's method has been shown to be superior to alternative approaches and to form very homogeneous clusters (Punj and Stewart 1983; Milligan and Cooper 1985).

In the second stage of the clustering procedure, we performed a non-hierarchical k -means clustering using the same dataset. With k -means clustering, objects are iteratively classified based on their distance to some initial starting points of dimension k . While some k -means methods use randomly selected starting points, we employ the centroids of the initial cluster solution of Ward's method for this purpose (Ketchen and Shook 1996). Using this non-hierarchical procedure, we identify three clusters of crowdinvestors.

Finally, a comparison of the means of the input variables obtained from Ward's method with those of the k -means algorithm did not show any qualitative differences. Also, the application of the above described two-stage procedure for a randomly split sample has led to the same results as those derived from using the full sample. Thus, we find support for the reliability of the three-cluster solution.

4.2.3 Results

The results are presented in the dendrogram in Fig. 1 in the Appendix. Starting from the bottom, more and more clusters are grouped together when higher levels of dissimilarity (or lower levels of similarity) are accepted. A visual inspection of the dendrogram suggests three different groups of crowdinvestors.

In Table 2, we report the final cluster solution derived from the k -means clustering procedure, providing descriptive statistics for the input variables included in the cluster analysis for each of the identified clusters. We explore differences between the identified clusters using ANOVA and post-hoc Duncan tests. The distinct characteristics of crowdinvestors belonging to the three clusters can be described as follows.

Cluster 1 Crowdinvestors in cluster 1 comprise 61.29% of the sample. These individuals distinguish themselves from the rest of the crowdinvestors through the highest number of funded projects (2.56 projects on average, compared to an average of 1.69–2.01 for the other clusters), the lowest amount invested per project (EUR 156.57 on average, which is approximately half the average amount invested by the full sample of crowdinvestors), and the lowest share of innovative projects (27.43%, compared to more than 40% for Clusters 2 and 3). Also, with 566.92 investors per project, the average number of project backers tends to be the smallest (compared to the more than 900 investors for the other clusters). To sum up, crowdinvestors in cluster 1 tend to be relatively risk-averse investing small amounts in less innovative, less risky projects. Besides, the small number of project backers suggests that community aspects play a small role when making their investment decision. Cluster 1 seems to primarily pursue own financial interests while trying to keep the probability of financial losses small. We label this group the *Casual Investors*.

Table 2 Three-cluster solution for the explorative cluster analysis

Clustering variables	Mean values (SD)						ANOVA <i>F</i> value ^a	Post hoc mean difference test (Duncan) ^b
	Cluster 1 (<i>n</i> = 4564)		Cluster 2 (<i>n</i> = 2568)		Cluster 3 (<i>n</i> = 314)			
Projects	2.56	(3.50)	1.69	(1.41)	2.01	(2.59)	74.32*	1 > 2, 3
Invested amount	156.57	(206.30)	329.07	(387.39)	3298.55	(1400.06)	9052.27*	3 > 1, 2; 2 > 1
Investors	566.92	(153.09)	1182.49	(274.14)	915.19	(387.29)	6733.81*	2 > 1, 3; 3 > 1
Comments	1.69	(7.06)	1.36	(6.02)	2.26	(7.54)	3.52**	1, 3 > 2
Innovativeness	27.43	(37.80)	52.33	(44.80)	41.84	(44.03)	311.56*	2 > 1, 3; 3 > 1
Population (%)	61.29		34.49		4.22			
Cluster label	Casual Investors		Crowd Enthusiasts		Sophisticated Investors			

^a**p* < 0.001; ***p* < 0.05

^b*p* < 0.05

Cluster 2 This group comprises 34.49% of the sample. With only 1.69 investments and 1.36 posted comments on average, crowdinvestors in cluster 2 seem to be the least active group of investors on Companisto. However, they emphasize funding innovations; on average 52.33% of the backed projects are innovative, representing the highest share among the three clusters. Given that these crowdinvestors appear to be less concerned about the higher degree of uncertainty involved in funding innovations, they may be driven by pro-social factors and community benefits. This group of investors might possess a strong sense of community, as may be indicated by the highest number of investors per project (i.e., 1182.49 project backers on average). Sharing the goal of funding a specific project with many others increases the chances of success while providing investors also with a community benefit and the feeling to be a valuable part of an “uplifting force.” We label these individuals the *Crowd Enthusiasts*.

Cluster 3 The third cluster represents the smallest group of crowdinvestors (4.22% of the sample). This group stands out from the other clusters for the average funding amount of EUR 3298.55. These investors are likely to have more experience and to have undertaken thorough due diligence, making their relatively large investments economically reasonable. They know how to assess the quality of projects and their creators and where to access more complex information about the projects that are not provided in the project descriptions. Both their substantial investments and their active participation, as indicated by posting the most comments (on average 2.26), further suggest a relatively strong

dedication to the funded project as compared to investors in clusters 1 and 2. We label investors of cluster 3 the *Sophisticated Investors*.

4.2.4 Robustness check

We conduct robustness checks to test the sensitivity of the identified investor typology with respect to the size of the sample of crowdinvestors considered for the cluster analysis. In particular, we re-run the cluster analysis with the same set of input variables but using different investor subsamples. Subsamples are constructed according to the timing of the investment decision. In three separate robustness checks, we restricted the cluster analysis to investors who invested in the first nine, 12 and 14 projects listed on Companisto. In all three analyses, our typology of crowdinvestors turned out to be robust. This cluster structure further remained robust to a final subsample specification where we restricted the cluster analysis to investors with at least two investments (i.e., excluding investors who only invested once on Companisto).

5 How do crowdinvestor types differ in their investment decision?

Building upon the cluster analysis results, we now attempt to validate our typology of crowdinvestors. We develop a set of hypotheses proposing how these distinct crowdinvestor types may react to project quality signals of entrepreneurs, project-related information reducing the degree of uncertainty and social influence by

fellow investors when making their investment decision. We consider four relevant mechanisms identified by the entrepreneurial finance literature: human capital of project creators, third-party certifications, financial projections and observed behavior of other investors.

5.1 Hypotheses

Project quality may be signaled to potential investors by the *human capital* of project creators. Generally, human capital encompasses an individual's skills and knowledge acquired through education, on-the-job training and other types of experience which may increase one's productivity at work (Becker 1964). Entrepreneurship researchers have investigated the influence of human capital on entrepreneurial success for over three decades (Unger et al. 2011). The importance of entrepreneurs' human capital is further highlighted by prior studies that suggest managerial skills and experience are among the selection criteria that are most frequently used by venture capitalists (Baum and Silverman 2004; Zacharakis and Meyer 2000).

Similarly, crowdinvestors perceive the qualifications and education of project creators as a reliable signal of project quality, see Ahlers et al. (2015), Li et al. (2016), Nitani and Riding (2017), and Piva and Rossi-Lamastra (2018) for related empirical evidence. Therefore, we expect a general tendency of crowdinvestors to fund projects of creators with higher levels of human capital. Due to their distinct profiles, however, such quality signals may not be perceived as equally important across the different types of crowdinvestors. In particular, Crowd Enthusiasts and Sophisticated Investors tend to invest more in innovative projects than Casual Investors. Since innovative investments reflect a higher degree of uncertainty regarding both the probability and magnitude of economic returns, Crowd Enthusiasts and Sophisticated Investors might more strongly rely on signals of project quality related to human capital of the entrepreneurs than Casual Investors. Therefore, we hypothesize:

Hypothesis 1: Crowd Enthusiasts and Sophisticated Investors are more likely to invest in projects whose creators signal human capital than Casual Investors.

Besides signals provided by the project creators, potential investors may also look for *external*

certifications of project quality. In the context of CI, Ralcheva and Roosenboom (2016) analyze three signaling mechanisms, in which a third party is involved. Ventures with business angel backing, grants, and intellectual property rights have significantly increased chances of success. Furthermore, Bapna (2019) studies the effect of certification by expert intermediaries on the tendency to invest.

Again, taking investor heterogeneity into account, we expect such external certifications not to be of equal importance to all crowdinvestor types. We argue that entrepreneurs' external certifications about project quality are relatively more important to Casual Investors. Sophisticated Investors tend to be experienced and more knowledgeable regarding reliable indicators of future project success (e.g., business plan, patents held, industry outlook). They know how to gather this information elsewhere in case it is not provided by the project creators, which makes them less likely to rely on third-party certifications of project quality. Crowd Enthusiasts' are less concerned with making a profit; instead, they have the desire to support project creator and cause. They tend to invest in a project if the business idea convinces them. Whether projects provide external certifications then seems to be of secondary relevance for them. Thus, we propose the following hypothesis:

Hypothesis 2: Casual Investors are more likely to invest in projects that provide third-party certifications than Crowd Enthusiasts and Sophisticated Investors.

Informational asymmetries between investor and entrepreneur are a key challenge in CI (Agrawal et al. 2014). If the degree of information asymmetry is too high and the supply of projects of inferior quality is relatively higher than the supply of good quality projects, markets of venture financing, such as CI, might even collapse. In order to attract funding, entrepreneurs need to provide reliable information that helps reduce the degree of uncertainty regarding the quality of the start-up project (Ireland et al. 2003). For instance, disclosing *financial projections* facilitates potential investors forming of expectations of the start-up's future returns, detailing the risks and opportunities of the investment. See Michael (2009) for similar evidence from the franchise sector and Ahlers et al. (2015) who find a positive link between the

disclosure of financial information (like roadmaps) and the funding success of CI campaigns.

Following previous research, there should also be a positive relationship between the provision of financial projections and the likelihood that a project receives investments in our data. We argue however that the assessment of financial projections disclosed by entrepreneurs differs across crowdfunder types. Crowd Enthusiasts' portfolios contain the highest share of innovative projects. In order to make their investment choices, they may focus on a project's idea, its vision, while they may put less emphasis on expected economic outcomes. By contrast, Casual Investors are mainly motivated by financial interests. They tend to keep the probability of financial losses small by diversifying their investments among less innovative (and therefore less risky) projects. Thus, Casual Investors are likely to strongly rely on information directly related to possible future outcomes most strongly. This assumption is in line with other research demonstrating that disclosed financial information is particularly appealing to risk-averse investors (Epstein and Schneider 2008). Sophisticated Investors tend to have a professional approach to investing. While they are open to risky investments in innovative projects, they also consider provided financial projections when they decide on an investment. Accordingly, we hypothesize:

Hypothesis 3: Casual Investors and Sophisticated Investors are more likely to invest in projects that provide information about financial projections than Crowd Enthusiasts.

Recent research on CF and CI stresses the role of *social influence* for the funder's decision to invest. The availability of information concerning the timing and the number of investments are found to be critical factors affecting the investment behavior of subsequent funders. In this context, empirical findings have been related to economic models of herding behavior (Herzenstein et al. 2011; Lee and Lee 2012; Zhang and Liu 2012; Colombo et al. 2015; Crosetto and Regner 2018; Vismara 2018) or substitution (i.e., crowding-out; Burch et al. 2013). Lin et al. (2014) find that whether crowding-out or herding takes place depends on the backer's motivation to engage in CF. They show that with an increasing number of backers the probability decreases that a project is chosen by users with altruistic motives to participate in CF. Likewise,

altruists do not seem to imitate the investment decision of experienced investors. On the contrary, risk-averse and reward-driven crowdfunders are found to imitate the decision of others, resulting in general herding behavior.

Based on these findings, we expect different responses to observed peer behavior along the crowdfunder typology. In particular, among the identified crowdfunder types, we expect Crowd Enthusiasts to most likely engage in herding behavior. Their investment portfolio accounts for the highest share of innovative projects which are characterized by a particularly high degree of uncertainty. Moreover, Crowd Enthusiasts should be positively influenced by the project creators' expressed belief in the quality of the business idea. In the light of Crowd Enthusiasts' strong sense of community, this positive feeling may be reinforced when peers invest in the same project, eventually inducing the Crowd Enthusiasts to invest as well. In this respect, Casual Investors differ from Crowd Enthusiasts. Casual Investors pursue an investment strategy of risk-diversification among less innovative projects. With their investment decisions, they seem to rely on less ambiguous information which may not include the decision of other investors. Finally, Sophisticated Investors can be characterized as being more experienced and knowledgeable compared to Casual Investors and Crowd Enthusiasts. They tend to undertake thorough due diligence and primarily base their investment decisions on own knowledge and expertise. Therefore, we expect that investments of Sophisticated Investors are rather not influenced by others' investment decisions but instead are used for guidance, predominantly by Crowd Enthusiasts. The following hypothesis applies:

Hypothesis 4: Crowd Enthusiasts are more likely to follow the investment decisions of Sophisticated Investors than Casual Investors or Sophisticated Investors.

5.2 Estimation strategy

To test our hypotheses, we adopt a choice model (using probit regression) and investigate how crowdfunders select a start-up project for funding from a set of alternatives. We implement a binary choice task that indicates whether or not the crowdfunder decides to fund a particular project. Given that at any point in time there are multiple projects available for funding, we have to

construct a temporal choice set for each crowdfunder. Hence, for each instance when an investment is being made we identify the possible set of alternative projects, including the eventual choice.² We let Y_{it} represent the binary choice task of funding a particular project out of the temporal set of alternative projects i , which is available at time t representing the day of investment.³ Y_{it} returns 1 if crowdfunder j decides to fund the particular project and 0 otherwise. It is important to note though that the binary choice task Y_i may repeat over time. For example, the same investment alternatives are presented to different crowdfunders if they access Companisto at the same time. Consequently, their investment decisions are likely to be correlated. This could potentially lead to biased estimates. To correct for the temporal correlation of outcomes in our data, we used the generalized estimation equation (GEE; Zeger et al. 1988) approach. Essentially, GEE is an extension of the generalized linear model (GLM) but allows for the use of a correlation matrix structure which takes into account the lack of independence of observations. The main advantage of GEE resides in the unbiased estimation of population-averaged (marginal) regression coefficients despite possible misspecification of the correlation structure (Cui 2007). For our analysis, we used the commonly specified exchangeable correlation as the working correlation matrix.

As we are interested in the determinants of crowdfunders' investment decisions, we let $\mu_{it} = E(Y_{it})$ denote the marginal expectation of whether a start-up project of the temporal choice set i is funded in time t . The marginal expectation of investment depends on the vector of explanatory variables (project, creator, and crowdfunder characteristics), X_{ij} , through the probit link function $Probit(\mu_{it}) = X_{ij}\beta + v_i$, where v_i represents the stochastic term related to the choice set i which is assumed to be normally distributed.

Finally, common model selection criteria like Akaike's (1974) information criterion (AIC) cannot be applied as GEE is a quasi-likelihood-based method (Cui 2007). Pan (2001) proposed the independence model

criterion (QIC) which is equivalent to the AIC in evaluating the goodness-of-fit of competing models.

5.3 Measures

5.3.1 Dependent variable

Our dependent variable is a dummy variable denoting whether a start-up project has been chosen for investment. The variable is coded as 1 if the project is chosen by the crowdfunder and 0 otherwise.

5.3.2 Explanatory variables

We use three dummy variables indicating membership of a crowdfunder to one of the three clusters: *Casual Investors* (0 = no, 1 = yes), *Crowd Enthusiasts* (0 = no, 1 = yes), and *Sophisticated Investors* (0 = no, 1 = yes). The former cluster served as reference group.

Furthermore, we employ a set of explanatory variables to account for differences in the responses of the crowdfunder types to signals of project quality and social influence, i.e., human capital of project creators, third-party certifications, financial projections and observed behavior of investor peers. The respective information has been collected from project pages at Companisto.

We use the educational level of project creators as a measure of human capital. Formal education may provide a broader set of knowledge, skills, and perspectives and may help mitigate the legitimacy problems start-ups face (Unger et al. 2011). Previous research showed that educational degrees of entrepreneurs, as part of their human capital, are a valid signal for a start-up's quality (Backes-Gellner and Werner 2007; Levie and Gimmon 2008; Ahlers et al. 2015; Nitani and Riding 2017; Piva and Rossi-Lamastra 2018). We use a PhD degree as a proxy for project creators' educational level. The corresponding dummy variable *PhD* equals one if at least one member of the project team claims to possess a PhD degree.

Regarding third-party endorsement, both Shane and Stuart (2002) and Hsu (2007) found that previously established social ties with third parties, such as VCs or business angels, increased the chances of an entrepreneur receiving external financing. The central premise of this research is that start-ups may benefit from performance implications of affiliating with resource providers with established reputations. In the context

² See Fig. 2 in the Appendix for a graphical illustration of the temporal overlap of projects' durations.

³ While this approach takes investors' choice sets into account, we do not know, of course, whether investors indeed consider all available investment alternatives. In the same vein, our analysis does not take into account that investors may have investment opportunities outside of Companisto.

of CI, Ralcheva and Roosenboom (2016) as well as Bapna (2019) employ connections with expert intermediaries in order to proxy external certification. Our dummy variable *Ties* returns 1 or 0 to indicate whether the start-up project has advertised a direct business or social relationship to a VC or angel investor before the start of the funding campaign.

The variable *Financial forecast* indicates whether a start-up project discloses financial projections to potential investors (0 = no, 1 = yes). The effect of disclosing financial forecasts has already been analyzed within franchising (Michael 2009) and with data from a CI platform (Ahlers et al. 2015). Since there is no standard procedure how to provide financial projections on Companisto, we consider statements in the project description about planned revenues, expenditures, earnings before interest and taxes as well as the return on sales.

Measures of social influence are typically based on the number of investors, the amount invested or specific investor types being present at a funding campaign within a defined period after the start of the campaign. For example, herding behavior is usually identified if one of the three measures of social influence positively correlates with a higher number of subsequent investors (cf. Colombo et al. 2015; Crosetto and Regner 2018; Hornuf and Schwiendbacher 2018; Vismara 2018). The approach applied in this paper differs. We take the investor's perspective to determine the effect of peer investor behavior on the individual decision about which project to fund, accounting for all alternatives being present at the time of investment. Similarly, Lin et al. (2014), in their study on reward-based CF, measured the presence of rational herding by the number of a specific crowdfunder type that had already pledged when the focal crowdfunder was presented with the project choice. To account for the influence of observed peer behavior, the variable *Sophisticated Investors_before* measures the number of Sophisticated Investors that have already invested in the alternatives presented to each investor, at the point in time an investment decision is made.

5.3.3 Control variables

The regression analysis employs control variables which might potentially influence the investment decision of crowdfunders. Lin et al. (2014) show that investors may back campaigns at a later funding stage

in order to observe the behavior of other investors before they decide in which project to invest. Hence, the control variable *Days after project start* captures the number of days elapsed since the start of the campaign when the investment was made, relative to the total number of funding days of the campaign (multiplied by 100). We also control for the size of the founding team. Team size has been shown to positively affect external evaluations of the business idea (Foo et al. 2005), the investment decisions of VCs (Kirsch et al. 2009) and of crowdfunders (Ahlers et al. 2015; Li et al. 2016; Vismara 2018). Therefore, the control variable *Team members* is a count of the members of the team of project creators. Moreover, we consider awards won, for example in business plan competitions, as a control variable to indicate external certifications of start-up quality. Winning an award may provide a positive evaluation of the business plan or the business idea, which mitigates information problems and eases the selection process for investors. We use a dummy variable to indicate whether a start-up project has received an award (*Awards*; 0 = no, 1 = yes). Prior research demonstrates that updates posted by the project creators can be an essential source of information leading to an increase in the number of pledges (Mollick 2014; Hornuf and Schwiendbacher 2018; Block et al. 2018b). To control for this effect, the variable *Updates* takes the value 1 if at least one update was posted within 3 days before the investment decision of the focal crowdfunder and 0 otherwise.

5.4 Results

Drawing upon the three crowdfunder profiles that we identified in the cluster analysis (see Sect. 4.2), we now study how the evaluation of investment alternatives differs across investor types. In particular, we are interested in the individual responses of Casual Investors, Crowd Enthusiasts, and Sophisticated Investors to various signals of project quality and social influence when making investment choices. This analysis contributes to a more detailed understanding of the heterogeneity of crowdfunders and their individual behavior on CI platforms.

For each investment made, we identify the possible set of alternative projects to invest in at that point of time. This results in a dataset with 67,833 investment alternatives. Table 3 provides descriptive statistics, and Table 4 displays the correlation among the variables used for the regression analysis.

Table 3 Descriptive statistics for the variables used in the regression analysis

Variables	Mean	SD	Min	Median	Max
PhD	0.12	0.32	0	0.00	1
Ties	0.44	0.50	0	0.00	1
Financial forecast	0.18	0.38	0	0.00	1

Updates	0.29	0.45	0	0.00	1

n of observations = 67,883 investment alternatives presented to the crowdfunders at the time of investment

Table 5 reports the results of the GEE estimation for the prediction of investment decisions of crowdfunders. Model 1 is a baseline specification without considering our cluster variables. It can be regarded as a test whether we find support for the impact of human capital, third-party certifications, financial projections, and observed behavior of other investors in our sample without distinguishing investor types. The coefficients for PhD ($\beta = 0.491$, $p < 0.001$) and Financial forecast ($\beta = 0.408$, $p < 0.001$) show up positive and significant. Crowdfunders, in general, seem to take into consideration the educational attainment of project creators and the availability of financial forecasts as project quality signal when selecting among investment alternatives. In contrast, the likelihood to attract an investment seems to diminish if a start-up project has pre-existing relationships with traditional investors (Ties; $\beta = -0.0358$, $p < 0.05$). The negative effect of Sophisticated Investors_before ($\beta = -0.0164$, $p < 0.001$) further suggests that crowdfunders, in

general, do not necessarily follow the investment decision of the group of Sophisticated Investors.

As regards the control variables, the team size (Team members; $\beta = 0.176$, $p < 0.001$) as well as recently posted updates (Updates; $\beta = 0.612$, $p < 0.001$) significantly and positively predict funding of a project. The number of days since the funding campaign has started (Days after project start; $\beta = -0.0129$, $p < 0.001$) and awards won (Awards; $\beta = -0.372$, $p < 0.001$) seem to have a negative effect on the investment choice of crowdfunders. Finally, Crowd Enthusiasts are relatively more likely to invest than Casual Investors, the reference group (Crowd Enthusiasts; $\beta = 0.0678$, $p < 0.001$), while there is no such difference between Sophisticated Investors and Casual Investors (Sophisticated Investors; $\beta = 0.0102$, *n. s.*).

Next, models 2 to 5 in Table 5 focus on differences in the prediction of investment decisions across the distinct types of crowdfunders in order to test hypotheses 1 to 4. Therefore, we include interaction effects between the

p* < 0.05; *p* < 0.01; ****p* < 0.001

cluster variables Casual Investors, Crowd Enthusiasts, and Sophisticated Investors on the one hand and the main explanatory variables PhD (model 2), Ties (model

3), Financial forecast (model 4), and Sophisticated Investors_before (model 5) on the other hand. The coefficients for the interaction effects are to be interpreted

relative to the baseline group Casual Investors. Hence, they indicate how much larger or smaller the parameter estimates for the respective explanatory variables are for Crowd Enthusiasts and Sophisticated Investors relative to Casual Investors. Table 6 further allows for a more detailed analysis of the coefficients for the interaction effects. Here, corresponding to models 2 to 5 in Table 5, the effect sizes for the parameter estimates of the main explanatory variables are reported. The effect size (see last column in Table 6) represents the percentage change in the predicted probability of a start-up project being chosen by an investor type before and after the value for the respective explanatory variable increased by one standard deviation (for continuous scales) or changed from 0 (base level) to 1 (for dummy variables), while keeping all other variables at their mean (for continuous scales) or median value (for dummy variables).

Turning to Hypothesis 1 and the proposed signaling effect of project creators' human capital on the likelihood to receive funding, model 2 in Table 5 provides positive and significant coefficients for Casual Investors ($\beta = 0.329$, $p < 0.001$), Crowd Enthusiasts ($\beta = 0.825$ ($0.329 + 0.496$), $p < 0.001$), and Sophisticated Investors ($\beta = 0.601$ ($0.329 + 0.272$), $p < 0.01$). Accordingly, it seems that higher levels of creator human capital are perceived as reliable project quality signal by all three crowdinvestor types. Interestingly, model 2 in Table 6 reveals significant differences among the three groups.

Accordingly, a change in the variable PhD from base level to 1 increases the likelihood that a project receives funding from the group of Crowd Enthusiasts by 213.76%. For Sophisticated Investors, a project creator holding a PhD increases the likelihood of investment by 145.44%, while the likelihood that Casual Investors choose a project is still 68.19% higher. In relative terms, however, Casual Investors are least likely to respond to higher levels of human capital in their investment decision. Therefore, hypothesis 1 is supported by the data. Moreover, our findings complement related results from other CI platforms stressing the importance of education (Ahlers et al. 2015; Nitani and Riding 2017; Piva and Rossi-Lamastra 2018).

Testing hypothesis 2, model 3 takes account of the signaling effect of third-party endorsement by venture capitalists or business angels (Ties). We find significant interaction effects for Crowd Enthusiasts ($\beta = -0.437$, $p < 0.001$) and Sophisticated Investors ($\beta = -0.242$, $p < 0.001$). Consequently, the coefficients for Crowd Enthusiasts and Sophisticated Investors are decreasing to $\beta = -0.366$ ($p < 0.001$) and $\beta = -0.171$ ($p < 0.001$), respectively. Crowd Enthusiasts and Sophisticated Investors seem to be less likely to invest in start-up projects when project creators possess preexisting ties to traditional investors. This is in strong contrast to Casual Investors ($\beta = 0.071$, $p < 0.001$). Table 6 reveals that this group is 13.31% more likely to invest in a project if

Table 6 Predicted probabilities and effect size of coefficients

Model	Variables	Cluster	Coefficient	Predicted probability		Effect size
				Before	After	
2	PhD	Casual investors	0.329**	0.11	0.18	68.19%
		Crowd enthusiasts	0.825**	0.11	0.34	213.76%
		Sophisticated investors	0.601*	0.10	0.25	145.44%
3	Ties	Casual investors	0.071**	0.10	0.11	13.31%
		Crowd enthusiasts	-0.366**	0.15	0.08	-46.40%
		Sophisticated investors	-0.171**	0.12	0.09	-25.48%
4	Financial forecast	Casual investors	0.474**	0.10	0.22	107.99%
		Crowd enthusiasts	0.289**	0.13	0.20	55.48%
		Sophisticated investors	0.474**	0.10	0.22	113.75%
5	Sophisticated investors_before	Casual investors	-0.033**	0.10	0.04	-61.84%
		Crowd enthusiasts	0.002**	0.10	0.10	4.75%
		Sophisticated investors	-0.009**	0.11	0.09	-21.87%

n of observations = 67,883 investment alternatives presented to the crowdinvestors at the time of investment

* $p < 0.01$; ** $p < 0.001$

there are existing relationships to external investors before the start of the funding campaign, while for Crowd Enthusiasts and Sophisticated Investors the likelihood to invest decreases by 46.4% and 25.48%, respectively. Overall, we find support for our hypothesis 2.

In model 4, we investigate differences in investment activities of the investor types in response to the provision of financial forecasts (hypothesis 3). Table 5 indicates that Casual Investors and Sophisticated Investors share the same parameter estimate for Financial forecast ($\beta = 0.474$, $p < 0.001$) since the interaction effect for Sophisticated Investors turns out not significant ($\beta = 0.0204$, *n. s.*). Thus, Casual Investors and Sophisticated Investors do not significantly differ in their response to provided financial forecasts. Table 6 further reveals that the likelihood to invest in projects increases for Casual Investors by 107.99% and for Sophisticated Investors by 113.75%, respectively, if financial forecasts are provided. Moreover, examining the effect size of the coefficient for Crowd Enthusiasts ($\beta = 0.289$, $p < 0.001$), we find that a change of the dummy variable Financial forecast from base level to 1 increases the probability to invest in the focal project by 55.48%. Taking these results together, we find strong support for the importance of financial information as project quality signal to reduce the degree of information asymmetry between project creators and investors. In more detail, though, Crowd Enthusiasts seem to be least likely to respond to this quality signal relative to the other two investor types. Hence, we find support for hypothesis 3.

Finally, model 5 tests for different responses to observed peer behavior along the crowdfunder typology (as proposed in hypothesis 4). Table 5 considers the interaction effects of the cluster membership variables and the explanatory variable Sophisticated Investors_before. The coefficient for Casual Investors is negative and statistically significant ($\beta = -0.0326$, $p < 0.001$), revealing that Casual Investors are less likely to follow more sophisticated peers in their investment decision. Assessing the economic magnitude of the coefficient in Table 6, a one standard deviation increase in the number of Sophisticated Investors that have already invested in a project (i.e., an increase from 20 to 35 Sophisticated Investors) leads to a decrease in the likelihood that Casual Investors will choose the same project by 61.84%. Similarly, for Sophisticated Investors, the likelihood to invest decreases by 21.87% ($\beta = -0.009$, $p < 0.001$) if the variable Sophisticated

Investors_before is increased by one standard deviation. In contrast, the coefficient of the interaction effect for Crowd Enthusiasts is positive and statistically significant (see Table 5; $\beta = 0.034$, $p < 0.001$) and even large enough to turn the negative coefficient of the baseline group from $\beta = -0.033$ ($p < 0.001$) to $\beta = 0.002$ ($p < 0.001$). In economic terms, Table 6 suggests that a one standard deviation increase of Sophisticated Investors_before leads to an increase in the likelihood that Crowd Enthusiasts will choose the project by 4.75%. Supporting hypothesis 4, Crowd Enthusiasts seem to be more likely to follow the investment decision of their more experienced and knowledgeable peers than the groups of Sophisticated Investors and Casual Investors, even though the economic magnitude of this response is rather small. Another important caveat for this result is the *first-come, first-serve* mechanism adopted by Companisto. As the funding mechanism induces quick investments at the early stages of a funding campaign, it may even impede herding behavior. Investors might feel inclined to invest early, forgoing the possibility to wait and observe the decision of others first.

5.5 Robustness check

Building on the robustness check of our cluster analysis that confirmed our typology of crowdfunders with a sample restricted to the first nine, 12 and 14 projects we now test the robustness of our regression results. We start with a subsample that includes the last ten projects and add further projects one by one in order to see, whether regression results remain qualitatively equal to the full sample when only these observations are considered. While the regression model does not converge when the restricted sample includes only the last 16 projects or less, our results are confirmed when the restricted sample excludes the first 11 projects (or less). Coefficient signs and significance levels are the same as in the entire sample results for all main and interaction effects.

6 Discussion

Given the recent rise of crowdfunding, especially crowdfundering (CI), this paper aims to contribute to a more thorough understanding of the “crowd.” We identify distinct investor types with different investment strategies and motivations. Consequently, we assess

the decision-making process of these individual investor types regarding the selection of investment opportunities, while accounting for the importance of project quality signals and social influence concerning the funding behavior of other investors.

Our analysis identifies three different crowdfunder types: a relatively small group of very active and experienced funders (the Sophisticated Investors), a sizable group of funders that are motivated by pro-social/community factors (the Crowd Enthusiasts), while the majority of funders seems mostly concerned about monetary returns (the Casual Investors).

These findings add to the literature that regards the crowd as a heterogeneous community and aims to identify differences in behavior (Hornuf and Schmitt 2016; Hervé et al. 2019; Mohammadi and Shafi 2018; Günther et al. 2018). With respect to crowdfunders' motivations, our results confirm previous research that crowdfunders are not exclusively motivated by financial returns but also by pro-social or community motives (Gerber et al. 2012; Belleflamme et al. 2014; Bretschneider and Leimeister 2017). Our results suggest that a sizable "pro-social" type not only exists in reward-based CF (see Lin et al. 2014) but also in the domain of CI.

In the second stage of our analysis, we take these insights about distinct crowdfunder types to the investment level in order to study individual choices. We test crowdfunders' response to project quality signals previously established by existing studies (Ahlers et al. 2015; Li et al. 2016; Ralcheva and Roosenboom 2016; Nitani and Riding 2017; Piva and Rossi-Lamastra 2018; Bapna 2019) without distinguishing by investor types.

First, this individual-level analysis complements other studies methodologically as they are mostly performed at the project level. Second, our analysis reveals that only human capital appears to be a general signal among the crowd. While investor type-specific effect sizes differ significantly, they are all positive. Instead, external certifications seem to be a signal that is only considered by Casual Investors. Also financial projections do not seem to be a universal signal for the crowd as Crowd Enthusiasts do not respond to them.

Moreover, our findings show that the majority of investors, i.e., the group of Casual Investors, do not seem inclined to follow the investment decisions of more sophisticated investors. At first glance, this result appears to contradict the findings of Vismara (2018): at the platform Crowdcube investors with a public profile

play a crucial role in triggering information cascades. Possibly, investors who possess superior knowledge are not salient enough at Companisto in order to make other investors rely on their funding decisions. We verified this with information about crowdfunders' membership in the Companisto Business Club. A badge next to an investor's name indicates membership in the club. As we do not have data about membership directly we use the underlying ranking (the top 10% of ranked investors are awarded membership).⁴ Checking the overlap between the ranking data and our classification of investors shows that Sophisticated Investors are indeed relatively overrepresented among the top 10% of ranked investors. However, membership is not exclusive to Sophisticated Investors, also many Crowd Enthusiasts and Casual Investors are club members. Thus, being a Sophisticated Investor is not a signal that can be clearly observed, a possible explanation for the lack of information cascades.

These insights about the heterogeneous composition of crowdfunders, their motivations to fund a campaign and their response to quality signals as well as peer behavior should be of interest for managers of CI platforms and entrepreneurs alike. This has implications for the design choices at CI platforms as they may affect the investment behavior of its participating investors. The trade-off between investor protection and start-up stimulation under current securities regulation of equity-based CF is well recognized (see Bradford 2012; Griffin 2013; Hornuf and Schwienbacher 2017). Policy intervention can achieve increased protection, for example, by setting standards for the provision of adequate information by entrepreneurs and platforms. A promising alternative avenue to decrease the potential abuse of less sophisticated investors may well be to improve platform design and alleviate information transmission from knowledgeable investors to the crowd. Our results confirm that sophisticated investors are a part of the crowd, see also Abrams (2017) for related evidence. Therefore, the pre-requisites appear to exist for beneficial knowledge spillovers within the crowd.

Naturally, our study is not without limitations. First of all, as noted by Lin et al. (2014), over time learning most likely will take place. As a consequence, more and

⁴ Companisto ranks investors depending on the number of start-ups in the portfolio, the money invested and the completeness of the profile, among other factors.

more Casual Investors may gain experience and might evolve into Sophisticated Investors. Our study is a snapshot at a relatively early point of time in the life of a CI platform. Thus, the fraction of Casual Investors should be regarded as an upper bound, while the fraction of Sophisticated Investors is likely to be a lower bound. A study at a more advanced point of time of a platform would provide valuable insights to what extent an evolution of types occurs.

Moreover, our cluster analysis is only one possible methodological approach to get insights about investor motivation. An alternative way to find out about the

motivation of participating investors would be a qualitative survey analysis (e.g., Gerber et al. 2012, or Bretschneider and Leimeister 2017, in the context of reward-based CF). This would require interviewing investors about their motivation and potentially a more extensive range of variables concerning signaling mechanisms and social influence could be used. Such research would be a valuable complement to the methodological approach of our study.

Funding Information Open Access funding provided by Projekt DEAL.

Appendix

Table 7 Background information about the start-up projects

No.	Start-up project	Start date	End date	Funding goal	Total funding	Total funding days	Investors	Sector	Business idea
1	Doxter	6.6.2012	9.9.2012	25,000	100,000	96	392	Technology	Internet platform to book medical appointments online
2	ePortrait	22.8.2012	11.9.2012	25,000	100,000	21	377	Technology	Online service for creating biometric passport photos
3	Ludufactur	31.8.2012	1.11.2012	25,000	50,000	63	366	Technology	Customization of card and board games for the gift market
4	Movinary	30.9.2012	12.11.2012	25,000	100,000	44	395	Technology	Online service for creating videos from images
5	BetterTaxi	1.11.2012	4.12.2012	25,000	100,000	34	445	Technology	Mobile application for booking taxis via smartphone
6	livekritik.de	22.11.2012	22.3.2013	25,000	80,525	121	496	Technology	Online platform collecting reports and visitors reviews about cultural events such as stage plays, concerts, dance or readings
7	Meine-Spielzeugkiste	6.1.2013	17.1.2013	25,000	100,000	12	356	Retail	Rental subscription model enabling parents to borrow children's toys without having to buy them
8	swabr.com	4.2.2013	4.4.2013	25,000	55,640	60	406	Technology	Enterprise social network service for communications within a company
9	SponsoRun	25.2.2013	25.4.2013	25,000	73,935	60	421	Technology	Mobile application that rewards sportive activity with exclusive vouchers
10	Tame	18.3.2013	12.4.2013	25,000	250,000	26	736	Technology	Context search engine in real-time for Twitter
11	Foodist	11.4.2013	11.5.2013	25,000	175,000	31	550	Retail	Monthly subscription service that delivers a collection of gourmet products
12	SongFor	6.5.2013	5.7.2013	25,000	41,290	60	264	Technology	Online platform that enables users to personalize their music playlists by relating songs with their emotions and experiences
13	5 CUPS and some sugar	3.6.2013	2.7.2013	25,000	300,000	30	688	Food	Sells, manufactures and delivers customized and personalized
